MILESTONE 4

Project Description

This project aims to act as a centralized database for a theme park designed to integrate ticketing, hotel reservation systems, loyalty programs, and ride operations. By consolidating all customer and operational data into one platform, it enables staff and management to efficiently query customer data.

This project included creating an ER diagram to model the data, creating a relational schema based on this ER diagram, performing data normalization, and writing SQL DDL (data description language) for the normalized schema.

The final stage of our project involved creating a web application which allows users to view Customer data, and perform various queries on this data, such as finding which customers have rode all rides at the theme park, finding the average number of points by gender, finding how many total guests have visited the theme park in each calendar month and more. The user can also perform basic operations, such as inserting new Customers into the database, updating customer information, removing customers, filtering customers based on their attributes, and viewing only a subset of Customer attributes such as name, birthdate, etc.

Differences Between the Final Schema and Milestone 2 Schema

The final schema is nearly the exact same as the one we turned in, aside from changing the “Sex” attribute in Customer to the more broad attribute of “Gender”. This was done in order to allow more groups, enabling our Query 7 (Aggregation with GROUP BY) to have sufficiently complex output.
